Package ‘MDPtoolbox’

February 19, 2015

Type Package
Title Markov Decision Processes toolbox
Version 4.0.2
Date 2014-07-21
Author Iadine Chades, Guillaume Chapron, Marie-Josee Cros, Frederick Garcia, Regis Sabbadin
Maintainer Guillaume Chapron <gchapron@carnivoreconservation.org>
Description The Markov Decision Processes (MDP) toolbox proposes functions related to the resolution of discrete-time Markov Decision Processes: finite horizon, value iteration, policy iteration, linear programming algorithms with some variants and also proposes some functions related to Reinforcement Learning.

References

**Examples**

```r
# Generates a random MDP problem
set.seed(0)
mdp_example_rand(2, 2)

# Generates a MDP for a simple forest management problem
MDP <- mdp_example_forest()

# Find an optimal policy
results <- mdp_policy_iteration(MDP$P, MDP$R, 0.9)

# Visualise the policy
results$policy
```

**mdp_bellman_operator**  
*Applies the Bellman operator*

---

**Description**

Applies the Bellman operator to a value function $V_{prev}$ and returns a new value function and a $V_{prev}$-improving policy.

**Usage**

`mdp_bellman_operator(P, PR, discount, Vprev)`

**Arguments**

- **P**  
  transition probability array. $P$ can be a 3 dimensions array $[S,S,A]$ or a list $[[A]]$, each element containing a sparse matrix $[S,S]$.

- **PR**  
  reward array. $PR$ can be a 2 dimension array $[S,A]$ possibly sparse.

- **discount**  
  discount factor. discount is a real number belonging to $[0; 1]$.

- **Vprev**  
  value function. $V_{prev}$ is a vector of length $S$.

**Details**

`mdp_bellman_operator` applies the Bellman operator: $PR + \text{discount} \times P \times V_{prev}$ to the value function $V_{prev}$. Returns a new value function and a $V_{prev}$-improving policy.

**Value**

- **V**  
  new value function. $V$ is a vector of length $S$.

- **policy**  
  policy is a vector of length $S$. Each element is an integer corresponding to an action.
Examples

# With a non-sparse matrix
p <- array(c(2, 2, 2), 2, 2, byrow=TRUE)
p[,] <- matrix(c(0.5, 0.5, 0.8, 0.2, 2, 2, byrow=TRUE)
p[,] <- matrix(c(0.1, 0.9, 2, 2, byrow=TRUE)
r <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_bellman_operator(p, r, 0.9, c(0,0))

# With a sparse matrix
p <- list()
p[,] <- Matrix(c(0.5, 0.5, 0.8, 0.2, 2, 2, byrow=TRUE, sparse=TRUE)
p[,] <- Matrix(c(0.1, 0.9, 2, 2, byrow=TRUE, sparse=TRUE)
mdp_bellman_operator(p, r, 0.9, c(0,0))

mdp_check

Checks the validity of a MDP

Description

Checks the validity of a MDP

Usage

mdp_check(P, R)

Arguments

P transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]],
each element containing a sparse matrix [S,S].

R reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element
containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

Details

mdp_check checks whether the MDP defined by the transition probability array (P) and the reward
matrix (R) is valid. If P and R are correct, the function returns an empty error message. In the
opposite case, the function returns an error message describing the problem.

Value

Returns a character string which is empty if the MDP is valid. In the opposite case, the variable
contains problem information
mdp_check_square_stochastic

Checks if a matrix is square and stochastic

Description

Checks whether a matrix is square and stochastic

Usage

mdp_check_square_stochastic(x)

Arguments

x  a matrix

Details

mdp_check_square_stochastic checks if the matrix (X) is square and stochastic (sums of rows equal to 1). If it is the case, the function returns an empty error message. In the opposite case, the function returns an error message describing the problem.

Value

Returns a character string which is empty if the matrix is square and stochastic. In the opposite case, the variable contains problem information.

Examples

M <- matrix(c(0.6116, 0.3884, 0, 1.0000), 2, 2, byrow=TRUE)

mdp_check_square_stochastic(M)
mdp_computePpolicyPRpolicy

Computes the transition matrix and the reward matrix for a fixed policy

Description

Computes the transition matrix and the reward matrix for a given policy.

Usage

mdp_computePpolicyPRpolicy(P, R, policy)

Arguments

P
  transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
R
  reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
policy
  a policy. policy is a length S vector of integer representing actions.

Details

mdp_computePpolicyPRpolicy computes the state transition matrix and the reward matrix of a policy, given a probability matrix P and a reward matrix.

Value

ppolicy
  transition probability array of the policy. Ppolicy is a [S,S] matrix.
prpolicy
  reward matrix of the policy. PRpolicy is a vector of length S.

Examples

# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.6116, 0.3884, 0, 1.0000), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0.6674, 0.3326, 0, 1.0000), 2, 2, byrow=TRUE)
R <- array(0, c(2,2,2))
R[,1] <- matrix(c(-0.2433, 0.7073, 0, 0.1871), 2, 2, byrow=TRUE)
R[,2] <- matrix(c(-0.0069, 0.6433, 0, 0.2898), 2, 2, byrow=TRUE)
policy <- c(2,2)
mdp_computePpolicyPRpolicy(P, R, policy)

# With a sparse matrix (P)
P <- list()
P[[1]] <- Matrix(c(0.6116, 0.3884, 0, 1.0000), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0.6674, 0.3326, 0, 1.0000), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_computePpolicyPRpolicy(P, R, policy)
**mdp_computePR**

Computes a reward matrix for any form of transition and reward functions.

**Description**

Computes the reward associated to a state/action pair.

**Usage**

```r
mdp_computePR(P, R)
```

**Arguments**

- **P**: transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
- **R**: reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

**Details**

`mdp_computePR` computes the reward of a state/action pair, given a probability array P and a reward array possibly depending on arrival state.

**Value**

**PR**: reward matrix. PR is a [S,A] matrix.

**Examples**

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.6116, 0.3884, 0, 1.0000), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0.6674, 0.3326, 0, 1.0000), 2, 2, byrow=TRUE)
R <- array(0, c(2,2,2))
R[,1] <- matrix(c(-0.2433, 0.7073, 0, 0.1871), 2, 2, byrow=TRUE)
R[,2] <- matrix(c(-0.0069, 0.6433, 0, 0.2898), 2, 2, byrow=TRUE)
mdp_computePR(P, R)

# With a sparse matrix (P)
P <- list()
P[[1]] <- Matrix(c(0.6116, 0.3884, 0, 1.0000), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0.6674, 0.3326, 0, 1.0000), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_computePR(P, R)
```
mdp_eval_policy_iterative

Evaluates a policy using an iterative method

Description

Evaluates a policy using iterations of the Bellman operator

Usage

mdp_eval_policy_iterative(P, R, discount, policy, V0, epsilon, max_iter)

Arguments

P transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].

R reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

discount discount factor. discount is a real number which belongs to [0; 1].

policy a policy. policy is a S length vector. Each element is an integer corresponding to an action.

V0 (optional) starting point. V0 is a S length vector representing an initial guess of the value function. By default, V0 is only composed of 0 elements.

epsilon (optional) search for an epsilon-optimal policy. epsilon is a real greater than 0. By default, epsilon = 0.01.

max_iter (optional) maximum number of iterations. max_iter is an integer greater than 0. If the value given in argument is greater than a computed bound, a warning informs that the computed bound will be used instead. By default, max_iter = 1000.

Details

mdp_eval_policy_iterative evaluates the value function associated to a policy applying iteratively the Bellman operator.

Value

Vpolicy value function. Vpolicy is a S length vector.

Examples

# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_eval_policy_matrix

Evaluates a policy using matrix inversion and product

Description

Evaluates a policy using matrix operation

Usage

mdp_eval_policy_matrix(p, r, discount, policy)

Arguments

p
transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].

r
reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

discount
discount factor. discount is a real number which belongs to [0; 1].

policy
a policy. policy is a S length vector. Each element is an integer corresponding to an action.

Details

mdp_eval_policy_matrix evaluates the value function associated with a policy

Value

Vpolicy value function. Vpolicy is a S length vector

Examples

# With a non-sparse matrix
P <- array(c(2,2),)
mdp_eval_policy_iterative(P, R, 0.8, policy)

P <- as.list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_eval_policy_iterative(P, R, 0.8, policy)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_eval_policy_iterative(P, R, 0.8, policy)

# With a sparse matrix

```r
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_eval_policy_matrix(P, R, 0.9, c(1,2))
```

---

**mdp_eval_policy_optimality**

*Computes sets of 'near optimal' actions for each state*

---

**Description**

Determines sets of 'near optimal' actions for all states

**Usage**

```r
mdp_eval_policy_optimality(P, R, discount, Vpolicy)
```

**Arguments**

- **P**: transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
- **R**: reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
- **discount**: discount factor. discount is a real number which belongs to [0; 1].
- **Vpolicy**: value function of the optimal policy. Vpolicy is a S length vector.

**Details**

For some states, the evaluation of the value function may give close results for different actions. It is interesting to identify those states for which several actions have a value function very close the optimal one (i.e. less than 0.01 different). We called this the search for near optimal actions in each state.

**Value**

- **multiple**: existence of at least two 'nearly' optimal actions for a state. multiple is egal to true when at least one state has several epsilon-optimal actions, false if not.
- **optimal_actions**: actions 'nearly' optimal for each state. optimal_actions is a [S,A] boolean matrix whose element optimal_actions(s, a) is true if the action a is 'nearly' optimal being in state s and false if not.
Examples

```r
# With a non-sparse matrix
P <- array(c(0, 1.5, 0, 0.5, 0.2), c(2, 2, 2))
P[1, 1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[1, 2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
Vpolicy <- c(42.4419, 36.0465)
mdp_eval_policy_optimality(P, R, 0.9, Vpolicy)

# With a sparse matrix
P <- list()
P[1] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[2] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_eval_policy_optimality(P, R, 0.9, Vpolicy)
```

mdp_eval_policy_TD_0  Evaluates a policy using the TD(0) algorithm

Description

Evaluates a policy using the TD(0) algorithm

Usage

`mdp_eval_policy_TD_0(P, R, discount, policy, N)`

Arguments

- `P`: transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
- `R`: reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
- `discount`: discount factor. discount is a real number which belongs to [0; 1].
- `policy`: a policy. policy is a S length vector. Each element is an integer corresponding to an action.
- `N` (optional) number of iterations to perform. N is an integer greater than the default value. By default, N is set to 10000

Details

`mdp_eval_policy_TD_0` evaluates the value function associated to a policy using the TD(0) algorithm (Reinforcement Learning).

Value

- `Vpolicy`: value function. Vpolicy is a length S vector.
Examples

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,]1 <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,]2 <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_eval_policy_TD_0(P, R, 0.9, c(1,2))

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_eval_policy_TD_0(P, R, 0.9, c(1,2))
```

```r
mdp_example_forest
Generates a MDP for a simple forest management problem
```

Description

Generates a simple MDP example of forest management problem

Usage

```r
mdp_example_forest(S, r1, r2, p)
```

Arguments

- `S` (optional) number of states. S is an integer greater than 0. By default, S is set to 3.
- `r1` (optional) reward when forest is in the oldest state and action Wait is performed. r1 is a real greater than 0. By default, r1 is set to 4.
- `r2` (optional) reward when forest is in the oldest state and action Cut is performed. r2 is a real greater than 0. By default, r2 is set to 2.
- `p` (optional) probability of wildfire occurrence. p is a real in ]0, 1[. By default, p is set to 0.1.

Details

`mdp_example_forest` generates a transition probability (SxSxA) array P and a reward (SxA) matrix R that model the following problem. A forest is managed by two actions: Wait and Cut. An action is decided each year with first the objective to maintain an old forest for wildlife and second to make money selling cut wood. Each year there is a probability p that a fire burns the forest.

Here is the modelisation of this problem. Let 1, ... S be the states of the forest. the Sth state being the oldest. Let Wait be action 1 and Cut action 2. After a fire, the forest is in the youngest state, that is state 1.
The transition matrix $P$ of the problem can then be defined as follows:

$$
P(\cdot, 1) = \begin{bmatrix}
p & 1-p & 0 & \cdots & \cdots & 0 \\
p & 1-p & 0 & \cdots & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\
\vdots & \vdots & \ddots & \ddots & 0 & \vdots \\
\vdots & \vdots & \ddots & \ddots & 1-p & \vdots \\
p & 0 & 0 & \cdots & 0 & 1-p
\end{bmatrix}
$$

$$
P(\cdot, 2) = \begin{bmatrix}
1 & 0 & \cdots & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
1 & 0 & \cdots & \cdots & 0
\end{bmatrix}
$$

The reward matrix $R$ is defined as follows:

$$
R(\cdot, 1) = \begin{bmatrix}
0 \\
\vdots \\
\vdots \\
\vdots \\
r_1
\end{bmatrix}
$$

$$
R(\cdot, 2) = \begin{bmatrix}
0 \\
1 \\
\vdots \\
\vdots \\
r_2
\end{bmatrix}
$$

Value

- $P$ transition probability array. $P$ is a $[S,S,A]$ array.
- $R$ reward matrix. $R$ is a $[S,A]$ matrix

Examples

```python
mdp_example_forest()
```
mdp_example_rand

Generates a random MDP problem

Description

Generates a random MDP problem

Usage

mdp_example_rand(S, A, is_sparse, mask)

Arguments

S  
number of states. S is an integer greater than 0
A  
number of actions. A is an integer greater than 0
is_sparse  
(optional) used to generate sparse matrices. is_sparse is a boolean. If it is set to true, sparse matrices are generated. By default, it is set to false.
mask  
(optional) indicates the possible transitions between states. mask is a [S,S] matrix composed of 0 and 1 elements (0 indicates a transition probability always equal to zero). By default, mask is only composed of 1.

Details

mdp_example_rand generates a transition probability matrix (P) and a reward matrix (R). Optional arguments allow to define sparse matrices and pairs of states with impossible transitions.

Value

P  
transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
R  
reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S]. Elements of R are in [-1; 1]

Examples

mdp_example_rand(2, 2)
mdp_example_rand(2, 2, FALSE)
mdp_example_rand(2, 2, TRUE)
mdp_example_rand(2, 2, FALSE, matrix(c(1,0,1,1),2,2))
**mdp_finite_horizon**  

Solves finite-horizon MDP using backwards induction algorithm

**Description**

Solves finite-horizon MDP with backwards induction algorithm

**Usage**

```
mdp_finite_horizon(P, R, discount, N, h)
```

**Arguments**

- **P**
  transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].

- **R**
  reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

- **discount**
  discount factor. discount is a real number which belongs to [0; 1[.

- **N**
  number of stages. N is an integer greater than 0.

- **h**
  (optional) terminal reward. h is a S length vector. By default, h = numeric(S).

**Details**

mdp_finite_horizon applies backwards induction algorithm for finite-horizon MDP. The optimality equations allow to recursively evaluate function values starting from the terminal stage. This function uses verbose and silent modes. In verbose mode, the function displays the current stage and the corresponding optimal policy.

**Value**

- **V**
  value function. V is a [S,(N+1)] matrix. Each column n is the optimal value function at stage n, with n = 1, ... N. V[N+1] is the terminal reward.

- **policy**
  optimal policy. policy is a [S,N] matrix. Each element is an integer corresponding to an action and each column n is the optimal policy at stage n.

- **cpu_time**
  CPU time used to run the program

**Examples**

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_finite_horizon(P, R, 0.9, 3)
```
# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_finite_horizon(P, R, 0.9, 3)

---

**mdp_LP**

Solves discounted MDP using linear programming algorithm

**Description**

Solves discounted MDP with linear programming

**Usage**

mdp_LP(P, R, discount)

**Arguments**

- **P** transition probability array. P is a 3 dimensions array [S,S,A]. Sparse matrix are not supported.
- **R** reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
- **discount** discount factor. discount is a real which belongs to [0; 1[

**Details**

mdp_LP applies linear programming to solve discounted MDP for non-sparse matrix only.

**Value**

- **V** optimal value function. V is a S length vector
- **policy** optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function
- **cpu_time** CPU time used to run the program

**Examples**

# Only with a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_LP(P, R, 0.9)
Solves discounted MDP using policy iteration algorithm

**Usage**

```plaintext
mdp_policy_iteration(P, R, discount, policy0, max_iter, eval_type)
```

**Arguments**

- **P**: transition probability array. P can be a 3 dimensions array \([S,S,A]\) or a list \([A]\), each element containing a sparse matrix \([S,S]\).
- **R**: reward array. R can be a 3 dimensions array \([S,S,A]\) or a list \([A]\), each element containing a sparse matrix \([S,S]\) or a 2 dimensional matrix \([S,A]\) possibly sparse.
- **discount**: discount factor. discount is a real which belongs to \([0; 1]\).
- **policy0**: (optional) starting policy. policy0 is a S length vector. By default, policy0 is the policy which maximizes the expected immediate reward.
- **max_iter**: (optional) maximum number of iterations to be done. max_iter is an integer greater than 0. By default, max_iter is set to 1000.
- **eval_type**: (optional) define function used to evaluate a policy. eval_type is 0 for mdp_eval_policy_matrix use, mdp_eval_policy_iterative is used in all other cases. By default, eval_type is set to 0.

**Details**

mdp_policy_iteration applies the policy iteration algorithm to solve discounted MDP. The algorithm consists in improving the policy iteratively, using the evaluation of the current policy. Iterating is stopped when two successive policies are identical or when a specified number (max_iter) of iterations have been performed.

**Value**

- **V**: optimal value function. V is a S length vector
- **policy**: optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function
- **iter**: number of iterations
- **cpu_time**: CPU time used to run the program
Examples

# With a non-sparse matrix
p <- array(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
p <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
r <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
mdp_policy_iteration(p, r, 0.9)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_policy_iteration(P, R, 0.9)

mdp_policy_iteration_modified
Solves discounted MDP using modified policy iteration algorithm

Description

Solves discounted MDP using modified policy iteration algorithm

Usage

mdp_policy_iteration_modified(P, R, discount, epsilon, max_iter)

Arguments

P  transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
R  reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
discount  discount factor. discount is a real number which belongs to [0; 1]. For discount equals to 1, a warning recalls to check conditions of convergence.
epsilon  (optional) search for an epsilon-optimal policy. epsilon is a real in [0; 1]. By default, epsilon = 0.01.
max_iter  (optional) maximum number of iterations to be done. max_iter is an integer greater than 0. By default, max_iter = 1000.

Details

mdp_policy_iteration_modified applies the modified policy iteration algorithm to solve discounted MDP. The algorithm consists, like policy iteration one, in improving the policy iteratively but in policy evaluation few iterations (max_iter) of value function updates done. Iterating is stopped when an epsilon-optimal policy is found.
### mdp_Q_learning

Solves discounted MDP using the Q-learning algorithm (Reinforcement Learning)

---

**Description**

Solves discounted MDP with the Q-learning algorithm (Reinforcement learning)

**Usage**

```r
mdp_Q_learning(P, R, discount, N)
```

**Arguments**

- **P**: transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
- **R**: reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
- **discount**: discount factor. discount is a real which belongs to ]0; 1[
- **N** (optional): number of iterations to perform. N is an integer that must be greater than the default value. By default, N is set to 10000.

---

**Value**

- **V**: optimal value function. V is a S length vector
- **policy**: optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function.
- **iter**: number of iterations
- **cpu_time**: CPU time used to run the program

---

**Examples**

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,,2] <- matrix(c(0.1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_policy_iteration_modified(P, R, 0.9)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0.1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_policy_iteration_modified(P, R, 0.9)
```
**Details**

`mdp_Q_learning` computes the Q matrix, the mean discrepancy and gives the optimal value function and the optimal policy when allocated enough iterations. It uses an iterative method.

**Value**

- **Q**: An action-value function that gives the expected utility of taking a given action in a given state and following an optimal policy thereafter. Q is a [S,A] matrix.
- **mean_discrepancy**: Discrepancy means over 100 iterations. mean_discrepancy is a vector of V discrepancy mean over 100 iterations. Then the length of the vector for the default value of N is 100.
- **V**: Value function. V is a S length vector.
- **policy**: Policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function.

**Examples**

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
# Not run
# mdp_Q_learning(P, R, 0.9)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
# Not run
# mdp_Q_learning(P, R, 0.9)
```

---

**mdp_relative_value_iteration**

Solves MDP with average reward using relative value iteration algorithm

**Description**

Solves MDP with average reward using relative value iteration algorithm

**Usage**

`mdp_relative_value_iteration(P, R, epsilon, max_iter)`
mdp_relative_value_iteration

Arguments

P transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].

R reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

epsilon (optional): search for an epsilon-optimal policy. epsilon is a real in [0; 1]. By default, epsilon is set to 0.01

max_iter (optional): maximum number of iterations. max_iter is an integer greater than 0. By default, max_iter is set to 1000.

Details

mdp_relative_value_iteration applies the relative value iteration algorithm to solve MDP with average reward. The algorithm consists in solving optimality equations iteratively. Iterating is stopped when an epsilon-optimal policy is found or after a specified number (max_iter) of iterations is done.

Value

policy optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function.

average_reward average reward of the optimal policy. average_reward is a real.

cpu_time CPU time used to run the program

Examples

# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_relative_value_iteration(P, R)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_relative_value_iteration(P, R)
mdp_span

Evaluates the span of a vector

Description

Computes the span of a vector.

Usage

mdp_span(W)

Arguments

W

a vector.

Details

mdp_span computes the span of the W vector: max W(s) - min W(s)

Value

the value of the span of the W vector.

mdp_value_iteration

Solves discounted MDP using value iteration algorithm

Description

Solves discounted MDP with value iteration algorithm

Usage

mdp_value_iteration(P, R, discount, epsilon, max_iter, V0)

Arguments

P

transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].

R

reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.

discount

discount factor. discount is a real number which belongs to [0; 1[. For discount equals to 1, a warning recalls to check conditions of convergence.

epsilonlon

(optional): search for an epsilon-optimal policy. epsilon is a real in ]0; 1[. By default, epsilon = 0.01.
mdp_value_iterationGS

Parameters:

max_iter (optional): maximum number of iterations. max_iter is an integer greater than 0. If the value given in argument is greater than a computed bound, a warning informs that the computed bound will be considered. By default, if discount is not equal to 1, a bound for max_iter is computed, if not max_iter = 1000.

V0 (optional): starting value function. V0 is a (Sx1) vector. By default, V0 is only composed of 0 elements.

Details

mdp_value_iteration applies the value iteration algorithm to solve discounted MDP. The algorithm consists in solving Bellman's equation iteratively. Iterating is stopped when an epsilon-optimal policy is found or after a specified number (max_iter) of iterations.

Value

policy: optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function.

iter: number of done iterations.

cpu_time: CPU time used to run the program.

Examples

# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,,2] <- matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_value_iteration(P, R, 0.9)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_value_iteration(P, R, 0.9)

mdp_value_iterationGS

Solves discounted MDP using Gauss-Seidel's value iteration algorithm.

Description

Solves discounted MDP with Gauss-Seidel's value iteration algorithm.

Usage

mdp_value_iterationGS(P, R, discount, epsilon, max_iter, V0)
**Arguments**

- **P**: transition probability array. P can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S].
- **R**: reward array. R can be a 3 dimensions array [S,S,A] or a list [[A]], each element containing a sparse matrix [S,S] or a 2 dimensional matrix [S,A] possibly sparse.
- **discount**: discount factor. discount is a real which belongs to ]0; 1]. For discount equals to 1, a warning recalls to check conditions of convergence.
- **epsilon** *(optional)*: search of an epsilon-optimal policy. epsilon is a real in ]0; 1]. By default, epsilon is set to 0.01.
- **max_iter** *(optional)*: maximum number of iterations to be done. max_iter is an integer greater than 0. If the value given in argument is greater than a computed bound, a warning informs that the computed bound will be considered. By default, if discount is not equal to 1, a bound for max_iter is computed, if not max_iter is set to 1000.
- **V0** *(optional)*: starting value function. V0 is a S length vector. By default, V0 is only composed of 0 elements.

**Details**

mdp_value_iterationGS applies Gauss-Seidel’s value iteration algorithm to solve discounted MDP. The algorithm consists, like value iteration, in solving Bellman’s equation iteratively \(V_{n+1}(s)\) calculation is modified. The algorithm uses \(V_{n+1}(s)\) instead of \(V_n(s)\) whenever this value has been calculated. In this way, convergence speed is improved. Iterating is stopped when an epsilon-optimal policy is found or after a specified number (max_iter) of iterations.

**Value**

- **policy**: epsilon-optimal policy. policy is a S length vector. Each element is an integer corresponding to an action which maximizes the value function.
- **iter**: number of done iterations.
- **cpu_time**: CPU time used to run the program.

**Examples**

```r
# With a non-sparse matrix
P <- array(0, c(2,2,2))
P[,1] <- matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE)
P[,2] <- matrix(c(0, 0.1, 0.9), 2, 2, byrow=TRUE)
R <- matrix(c(5, 10, -1, 2), 2, 2, byrow=TRUE)
mdp_value_iterationGS(P, R, 0.9)

# With a sparse matrix
P <- list()
P[[1]] <- Matrix(c(0.5, 0.5, 0.8, 0.2), 2, 2, byrow=TRUE, sparse=TRUE)
P[[2]] <- Matrix(c(0, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
mdp_value_iterationGS(P, R, 0.9)
```
### mdp_value_iteration_bound_iter

*Computes a bound for the number of iterations for the value iteration algorithm*

#### Description

Computes a bound on the number of iterations for the value iteration algorithm

#### Usage

\[
\text{mdp\_value\_iteration\_bound\_iter}(P, R, \text{discount}, \epsilon, V0)
\]

#### Arguments

- **P**
  - transition probability array. \( P \) can be a 3 dimensions array \([S, S, A]\) or a list \([A]\), each element containing a sparse matrix \([S, S]\).

- **R**
  - reward array. \( R \) can be a 3 dimensions array \([S, S, A]\) or a list \([A]\), each element containing a sparse matrix \([S, S]\) or a 2 dimensional matrix \([S, A]\) possibly sparse.

- **discount**
  - discount factor. discount is a real which belongs to \([0; 1]\).

- **epsilon**
  - (optional): search for an epsilon-optimal policy. \( \epsilon \) is a real in \([0; 1]\). By default, \( \epsilon \) is set to 0.01.

- **V0**
  - (optional): starting value function. \( V0 \) is a \( S \) length vector. By default, \( V0 \) is only composed of 0 elements.

#### Details

\( \text{mdp\_value\_iteration\_bound\_iter} \) computes a bound on the number of iterations for the value iteration algorithm to find an epsilon-optimal policy with use of span for the stopping criterion.

#### Value

- **max_iter**: maximum number of iterations to be done. \( \text{max\_iter} \) is an integer greater than 0.
- **cpu_time**: CPU time used to run the program.

#### Examples

\[
\begin{align*}
&\text{# With a non-sparse matrix} \\
&P \leftarrow \text{array}(0, c(2,2,2)) \\
&P[,1] \leftarrow \text{matrix}(c(0.5, 0.5, 0.8, 0.2), 2, 2, \text{byrow=TRUE}) \\
&P[,2] \leftarrow \text{matrix}(c(0, 1, 0.1, 0.9), 2, 2, \text{byrow=TRUE}) \\
&R \leftarrow \text{matrix}(c(5, 10, -1, 2), 2, 2, \text{byrow=TRUE}) \\
&\text{mdp\_value\_iteration\_bound\_iter}(P, R, 0.9)
\end{align*}
\]

\[
\begin{align*}
&\text{# With a sparse matrix} \\
&P \leftarrow \text{list}() \\
&P[[1]] \leftarrow \text{Matrix}(c(0.5, 0.5, 0.8, 0.2), 2, 2, \text{byrow=TRUE}, \text{sparse=TRUE})
\end{align*}
\]
P[2] <- Matrix(c(0, 1, 0.1, 0.9), 2, 2, byrow=TRUE, sparse=TRUE)
