Package ‘visreg’

February 25, 2015

Title Visualization of Regression Models
Version 2.1-1
Date 2014-02-25
Author Patrick Breheny, Woodrow Burchett
Maintainer Patrick Breheny <patrick-breheny@uiowa.edu>
Imports lattice
Suggests rgl, survival, MASS, nlme, splines, lme4
Description Provides a convenient interface for constructing plots to visualize the fit of regression models arising from a wide variety of models in R (lm, glm, coxph, rlm, gam, locfit, etc.)
License GPL-2

visreg-package  Visualization of regression models

Description

visreg provides a number of plotting functions for visualizing fitted regression models: regression functions, confidence bands, partial residuals, interactions, and more.

Details

This package allows the use of visreg and visreg2d, functions for visualizing regression models. See example below for the most basic use, and the help pages for each function for details. Also see the cited manuscript for additional details. If you have a question or feature request, please e-mail me at <patrick-breheny@uiowa.edu>.

   visreg(fit, "Wind")

plot.visreg  Visualization of regression functions

Description

A function for visualizing regression models quickly and easily. Default plots contain a confidence band, prediction line, and partial residuals. Factors, transformations, conditioning, interactions, and a variety of other options are supported. The plot.visreg function accepts a visreg or visreg.list object as calculated by visreg and creates the plot.
Usage

## S3 method for class 'visreg'
plot(x, overlay=FALSE, print.cond=FALSE, whitespace=0.2, partial=identical(x$meta$trans, 1), band=TRUE, rug=!partial, strip.names=is.numeric(x$fit[,x$meta$by]), legend=TRUE, line.par=NULL, fill.par=NULL, points.par=NULL, ...)

Arguments

x
A visreg or visreg.list object; see visreg.

overlay
When by is specified, by default separate panels are used to display each cross-section. If overlay=TRUE, these cross-sections are overlaid on top of each other in a single plot.

print.cond
If print.cond=TRUE, the explanatory variable values conditioned on in a conditional plot are printed to the console (default: FALSE). If print.cond=TRUE and type="contrast", the conditions will still be printed, but they have no bearing on the plot unless interactions are present.

whitespace
When xvar is a factor, whitespace determines the amount of space in between factors on the x-axis. Default is 0.2, meaning that 20 percent of the horizontal axis is whitespace.

partial
If partial=TRUE (the default), partial residuals are shown on the plot.

band
If band=TRUE (the default), confidence bands are shown on the plot.

rug
By default, partial residuals are plotted. Alternatively, a rug may be plotted along the horizontal axis instead. Setting rug=TRUE turns off partial residuals by default; if one wants both to be plotted, both rug=TRUE and partial=TRUE need to be specified. Two types of rug plots are available. If rug=1 or rug=TRUE, then a basic rug is drawn on the bottom. If rug=2, then separate rugs are drawn on the top for observations with positive residuals and on the bottom for observations with negative residuals. Such plots are particularly useful in logistic regression (see examples).

strip.names
When by=TRUE, strip.names=TRUE adds the name of the by variable to the strip at the top of each panel. Default is FALSE for factors and TRUE for numeric by variables. strip.names can also be a character vector, in which case it replaces the strip names altogether with values chosen by the user.

legend
For overlay plots, (overlay=TRUE), should visreg create a legend? If legend=TRUE (the default), a legend is placed in the top margin.

line.par
List of parameters (see par) to pass to lines(...) when lines are drawn in the plots.

fill.par
List of parameters (see par) to pass to polygon(...) when shaded confidence regions are drawn in the plots.

points.par
List of parameters (see par) to pass to points(...) when partial residuals are drawn in the plots.

...
Graphical parameters can be passed to the function to customize the plots. If by=TRUE, lattice parameters can be passed, such as layout (see examples below).
visreg

Visualization of regression functions

Description

A function for visualizing regression models quickly and easily. Default plots contain a confidence band, prediction line, and partial residuals. Factors, transformations, conditioning, interactions, and a variety of other options are supported. The `visreg` function performs the calculations and, if `plot=TRUE` (the default), these calculations are passed to `plot.visreg` for plotting.

Usage

\[
\text{visreg}(\text{fit, xvar, by, breaks=3, type=c("conditional", "contrast", "effect"), trans=I, scale=c("linear","response"), xtrans, alpha=.05, nn=101, cond=list(), jitter=FALSE, plot=TRUE, ...)}
\]

Arguments

- `fit` The fitted model object you wish to visualize. Any object with 'predict' and 'model.frame' methods are supported, including lm, glm, gam, rlm, coxph, and many more.
- `xvar` Character string specifying the variable to be put on the x-axis of your plot. Both continuous variables and factors are supported.
- `by` (Optional) A variable allowing you to divide your plot into cross-sections based on levels of the by variable; particularly useful for visualizing models with interactions. Supplied as a character string. Uses the lattice package. Both continuous variables and factors are supported.

Examples

```r
fit <- lm(Ozone ~ Solar.R + Wind + Temp, data=airquality)
visreg(fit, "Wind", line=list(col="red"), points=list(cex=1, pch=1))
## See ?visreg for more examples
```
visreg

breaks If a continuous variable is used for the by option, the breaks argument controls the values at which the cross-sections are taken. By default, cross-sections are taken at the 10th, 50th, and 90th quantiles. If breaks is a single number, it specifies the number of breaks. If breaks is a vector of numbers, it specifies the values at which the cross-sections are to be taken. Each partial residuals appears exactly once in the plot, in the panel it is closest to.

type The type of plot to be produced. The following options are supported:

- If 'conditional' is selected, the plot returned shows the value of the variable on the x-axis and the change in response on the y-axis, holding all other variables constant (by default, median for numeric variables and most common category for factors).
- If 'contrast' is selected, the plot returned shows the effect on the expected value of the response by moving the x variable away from a reference point on the x-axis (for numeric variables, this is taken to be the mean).

For more details, see references.

trans (Optional) A function specifying a transformation for the vertical axis.

scale By default, the model is plotted on the scale of the linear predictor. If scale='response' for a glm, the inverse link function will be applied so that the model is plotted on the scale of the original response.

xtrans (Optional) A function specifying a transformation for the horizontal axis. Note that, for model terms such as log(x), visreg automatically plots on the original axis (see examples).

alpha Alpha level (1-coverage) for the confidence band displayed in the plot (default: 0.05).

nn Controls the smoothness of the line and confidence band. Increasing this number will add to the computational burden, but produce a smoother plot (default: 101).

cond Named list specifying conditional values of other explanatory variables. By default, conditional plots in visreg are constructed by filling in other explanatory variables with the median (for numeric variables) or most common category (for factors), but this can be overridden by specifying their values using cond (see examples).

jitter Adds a small amount of noise to xvar. Potentially useful if many observations have exactly the same value. Default is FALSE.

plot Send the calculations to plot.visreg? Default is TRUE.

... Graphical parameters (e.g., ylab) can be passed to the function to customize the plots. If by=TRUE, lattice parameters can be passed, such as layout (see examples below).

Details

See plot.visreg for plotting options, such as changing the appearance of points, lines, confidence bands, etc.
Value

A visreg or visreg.list object (which is simply a list of visreg objects). A visreg object has three components:

- **fit**
  A data frame with \( nn \) rows containing the fit of the model as \( xvar \) varies, along with lower and upper confidence bounds (named `visregfit`, `visregLwr`, and `visregUpr`, respectively). The fitted matrix of coefficients.

- **res**
  A data frame with \( n \) rows, where \( n \) is the number of observations in the original data set used to model. This frame contains information about the residuals, named `visregRes` and `visregPos`; the latter records whether the residual was positive or negative.

- **meta**
  Contains meta-information needed to construct plots, such as the name of the x and y variables, whether there were any by variables, etc.

Examples

```r
# Linear models
# Basic
fit <- lm(Ozone ~ Solar.R + Wind + Temp, data=airquality)
visreg(fit)
visreg(fit, "Wind", type="contrast")
visreg(fit, "Wind", type="conditional")
visreg(fit, "Wind", type="conditional", rug=TRUE)
visreg(fit,c("Solar.R","Wind","Temp"))

# Factors
airquality$Heat <- cut(airquality$Temp,3,labels=c("Cool","Mild","Hot"))
fit.heat <- lm(Ozone ~ Solar.R + Wind + Heat, data=airquality)
visreg(fit.heat,"Heat",type="contrast")
visreg(fit.heat,"Heat",type="conditional")
# Use of whitespace option
visreg(fit.heat,"Heat",whitespace=.1)
visreg(fit.heat,"Heat",whitespace=.5)
```
## Transformations

```r
fit1 <- lm(Ozone ~ Solar.R + Wind + Temp + I(Wind^2), data=airquality)
fit2 <- lm(log(Ozone) ~ Solar.R + Wind + Temp, data=airquality)
fit3 <- lm(log(Ozone) ~ Solar.R + Wind + Temp + I(Wind^2), data=airquality)
visreg(fit1,"Wind")
visreg(fit2,"Wind", trans=exp, ylab="Ozone")
visreg(fit3,"Wind", trans=exp, ylab="Ozone")
```

## Conditioning

```r
visreg(fit, "Wind", cond=list(Temp=50))
visreg(fit, "Wind", print.cond=TRUE)
visreg(fit, "Wind", cond=list(Temp=100))
```

## Interactions

```r
fit.inl <- lm(Ozone ~ Solar.R + Wind+Heat, data=airquality)
visreg(fit.inl, "Wind", by="Heat")
visreg(fit.inl, "Heat", by="Wind")
visreg(fit.inl, "Wind", by="Heat", type="contrast")
visreg(fit.inl, "Wind", cond=list(Heat="Cool"), type="contrast")
visreg(fit.inl, "Wind", cond=list(Heat="Hot"), type="contrast")
visreg(fit.inl, "Heat", by="Wind", breaks=6)
visreg(fit.inl, "Heat", by="Wind", breaks=c(0,10,20))
```

## Overlay

```r
visreg(fit.inl, "Wind", by="Heat", overlay=TRUE)
visreg(fit.inl, "Wind", by="Heat", overlay=TRUE, partial=FALSE)
visreg(fit.inl, "Wind", by="Heat", overlay=TRUE, partial=FALSE, band=FALSE)
visreg(fit.inl, "Wind", by="Heat", overlay=TRUE, partial=FALSE, band=FALSE, type="contrast")
```

## Changing appearance

```r
visreg(fit, "Wind", line=list(col="blue"), points=list(cex=1, pch=1))
```

### Logistic regression

```r
data(birthwt, package="MASS")
birthwt$race <- factor(birthwt$race, labels=c("White","Black","Other"))
birthwt$smoke <- factor(birthwt$smoke, labels=c("Nonsmoker","Smoker"))
fit <- glm(low~age+race+smoke+lwt, data=birthwt, family="binomial")
visreg(fit, "lwt", xlab="Mother's Weight", ylab="Log odds (low birthweight)")
visreg(fit, "lwt", scale="response", partial=FALSE, xlab="Mother's Weight", ylab="P(low birthweight)")
visreg(fit, "lwt", scale="response", partial=FALSE, xlab="Mother's Weight", ylab="P(low birthweight)", rug=2)
```

## Proportional hazards

```r
require(survival)
data(ovarian)
ovarian$rx <- factor(ovarian$rx)
fit <- coxph(Surv(futime,fustat)~age+rx, data=ovarian)
```
Description

This page tries to answer some of the questions that I get asked most often about how to use the visreg package. If you have a question that does not appear below, I can be reached at <patrick-breheny@uiowa.edu>.

Frequent asked questions

1. **What is the difference between 'conditional' and 'contrast' plots?**

   Suppose our data looked like:

<table>
<thead>
<tr>
<th>SBP</th>
<th>Sex</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>140</td>
<td>M</td>
<td>56</td>
</tr>
<tr>
<td>135</td>
<td>F</td>
<td>47</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   we fit a model with

   ```r
   fit <- lm(SBP~Sex+Age)
   ```

   and we want to plot the relationship between Age and SBP. A 'conditional' plot illustrates the relationship between the two, conditional on the sex being, say, Male (the default in visreg is to choose the most common category).

   The 'contrast' plot in visreg, on the other hand, illustrates the effect on SBP of a change in age – the default in visreg is to use the mean age as the reference point for this change. Since the above model does not have an interaction, this effect will be the same for men and women, and thus does not require you to specify a sex for the plot.

   Both conditional and contrast plots answer subtly different questions, and both are useful in different situations.

2. **Can visreg can be used for mixed models (i.e., from the 'nlme' or 'lme4' packages)?**

   Sort of. The underlying basis on which visreg operates is by using the predict method to plot predictions from the model. Predictions for mixed models are complicated. In particular, there

```r
visreg(fit, "age", ylab = "log(Hazard ratio")

## Robust regression
require(MASS)
fit <- rlm(Ozone ~ Solar.R + Wind+Heat, data=airquality)
visreg(fit, "Wind", cond = list(Heat = "Mild"))

## And more...; anything with a 'predict' method should work

## Return raw components of plot
v <- visreg(fit, "Wind", cond = list(Heat = "Mild"))
```
is no se.fit option provided by the predict methods in the \texttt{nlme} and \texttt{lme4} packages, so you cannot obtain confidence bands for conditional plots. Nevertheless, \texttt{visreg} will produce plots of estimated coefficients and partial residuals.

In addition, there may be certain nesting structures among the covariates that \texttt{visreg} cannot be aware of; for example, if you are trying to plot the effect of age for various individuals, fixing sex at \texttt{sex=Male}, this may involve setting the sex of female subjects to \texttt{Male} for the sake of the plot. Whether such a plot has any meaning, you will have to judge for yourself. In general, contrast plots are more trustworthy than than conditional plots, given the intricacies of setting up conditions in a hierarchical model.

Keep in mind that depending on what sort of predictions (BLUPs) you are interested in, you may need to manually control the inclusion of random effects in your predictions. By default, \texttt{visreg} includes no random effects (i.e., \texttt{level=0} for \texttt{nlme} models and \texttt{re.form=NA} for \texttt{lme4} models). If you are including a random effect as a by variable in \texttt{visreg}, you most likely want to add those effects back in, and you will have to do so manually, by directly specifying the appropriate level or \texttt{re.form} argument to \texttt{predict} (see \texttt{?predict.nlme} or \texttt{?predict.lmerMod}). Handling this appropriately is the user’s responsibility; I cannot hope to automatically decide this for all possible mixed models that could be passed to \texttt{visreg}.

As mentioned above, you cannot obtain confidence bands for conditional plots. In the words of the authors of the \texttt{lme4} package, “There is no option for computing standard errors of predictions because it is difficult to define an efficient method that incorporates uncertainty in the variance parameters”; hence no se.fit option. You can, however, get confidence bands for ‘contrast’ plots. In a contrast plot, the random effects cancel and the above issue is avoided.

If you are running into difficulty using \texttt{visreg} with mixed models, feel free to e-mail me; mixed models have been less extensively tested with \texttt{visreg} than fixed-effect models, and there may still be bugs to work out.

3. \textbf{How do I use \texttt{visreg} for a model with offset terms?}

By default, \texttt{visreg} is set up to provide conditional plots in which all other terms are set to their median value (or most common category). This includes offset terms. It is not uncommon, however, to want to see results with the offset included. To obtain these results, one needs to specify the offset among the arguments to \texttt{cond}. For example, using the Insurance data from the \texttt{MASS} package:

\begin{verbatim}
utils::data(Insurance, package="MASS")
fit <- glm(Claims ~ District + Group + Age + offset(log(Holders)), data = Insurance, family = poisson)
visreg(fit, "Group", scale="response")
\end{verbatim}

This will provide the model’s predictions for the expected number of claims given the median number of holders (here, 136). To obtain the expected number of claims per holder, we need to specify Holders=1 in \texttt{cond}:

\begin{verbatim}
visreg(fit, "Group", scale="response", cond=list(Holders=1))
\end{verbatim}

Note also that to ensure proper functionality with all of \texttt{visreg}'s options, the use of the \texttt{offset()} function, rather than the \texttt{offset=} argument, is recommended.

4. \textbf{Why doesn’t \texttt{visreg} work with models I fit with package XXX?}

\texttt{visreg()} relies on being able to call certain generic functions to interface with the fitted model object that is passed to it. Specifically, if \texttt{fit} is the fit of a model that is passed to \texttt{visreg}, the following have to work:
model.frame(fit) formula(fit)

If they do not, there is nothing I can really do on the visreg end to get it to work – the author of the package would need to add support for those generic functions to make it more portable. If the above lines of code do work and visreg still fails, please let me know – perhaps there is a bug somewhere that I can fix.

visreg2d

Visualization of regression functions for two variables

Description

A function used to visualize how two variables interact to affect the response in regression models.

Usage

visreg2d(fit, xvar, yvar, type=c("conditional", "contrast", "effect"),
trans=1, scale=c("linear","response"),
plot.type=c("image","persp","rgl"), nn=ifelse(plot.type=="persp",49,99),
cond=list(), print.cond=FALSE, whitespace=0.2, ...)

Arguments

fit       The fitted model object you wish to visualize. Any object with 'predict' and 'model.frame' methods are supported, including lm, glm, gam, rlm, coxph, and many more.
xvar      Character string specifying the variable to be put on the x-axis of your plot. Both continuous variables and factors are supported.
yvar      Character string specifying the variable to be put on the y-axis of your plot. Both continuous variables and factors are supported.
type      The type of plot to be produced. The following options are supported:

  • If 'conditional' is selected, the plot returned shows the value of the variable on the x-axis and the change in response on the y-axis, holding all other variables constant (by default, median for numeric variables and most common category for factors).
• If 'contrast' is selected, the plot returned shows the effect on the expected value of the response by moving the x variable away from a reference point on the x-axis (for numeric variables, this is taken to be the mean).

For more details, see references.

trans
(Optional) A function specifying a transformation for the vertical axis.

scale
By default, the model is plotted on the scale of the linear predictor. If scale='response' for a glm, the inverse link function will be applied so that the model is plotted on the scale of the original response.

plot.type
The style of plot to be produced. The following three options are supported:
• 'image', a filled contour plot.
• 'persp', a 3 dimensional perspective plot.
• 'rgl', a version of the perspective plot that can be rotated. Note: requires the rgl package to use.

nn
Resolution of the three dimensional plot. Higher values will result in a smoother looking plot.

cond
Named list specifying conditional values of other explanatory variables. By default, conditional plots in visreg are constructed by filling in other explanatory variables with the median (for numeric variables) or most common category (for factors), but this can be overridden by specifying their values using cond (see examples).

print.cond
If print.cond==TRUE, the explanatory variable values conditioned on in a conditional plot are printed to the console (default: FALSE). If print.cond==TRUE and type=="contrast", the conditions will still be printed, but they have no bearing on the plot unless interactions are present.

whitespace
When xvar or yvar is a factor, whitespace determines the amount of space in between the factors. Default is 0.2, meaning that 20 percent of the axis is whitespace.

... Graphical parameters can be passed to the function to customize the plots.

Value
In addition to providing plots, the visreg2d function also invisibly returns the x, y, and Z values used in the creation of its plots.
