1 Overview of this and related documents

To do basic and advanced personality and psychological research using R is not as complicated as some think. This is one of a set of “How To” to do various things using R (R Core Team, 2023), particularly using the *psych* (Revelle, 2023) package.

The current list of How To’s includes:

1. An [introduction](#) (vignette) of the *psych* package
2. An [overview](#) (vignette) of the *psych* package
3. [Installing R](#) and some useful packages
4. Using R and the *psych* package to find ω_h and ω_t .
5. Using R and the *psych* for [factor analysis](#) and principal components analysis.
6. Using the `scoreItems` function to find [scale scores and scale statistics](#).
7. Using `mediate` and `lmCor` to do [mediation, moderation and regression analysis](#) (this document)

1.1 Jump starting the *psych* package—a guide for the impatient

You have installed *psych* and you want to use it without reading much more. What should you do?

1. Activate the *psych* and *psychTools* packages.

```
> library(psych)
> library(psychTools)
```

R code

2. Input your data. If your file name ends in `.sav`, `.text`, `.txt`, `.csv`, `.xpt`, `.rds`, `.Rds`, `.rda`, or `.RDATA`, then just read it in directly using `read.file`. Or you can go to your friendly text editor or data manipulation program (e.g., Excel) and copy the data to the clipboard. Include a first line that has the variable labels. Paste it into *psych* using the `read.clipboard.tab` command:

```
myData <- read.file()    #this will open a search window on your machine
#                        and read or load the file.
#or
#first copy your file to your clipboard and then
myData <- read.clipboard.tab() #if you have an excel file
```

R code

3. Make sure that what you just read is right. Describe it and perhaps look at the first and last few lines. If you want to “view” the first and last few lines using a spreadsheet like viewer, use `quickView`.

R code

```
describe(myData)
headTail(myData)
#or
quickView(myData)
```

4. Look at the patterns in the data. If you have fewer than about 10 variables, look at the SPLOM (Scatter Plot Matrix) of the data using `pairs.panels`.

R code

```
pairs.panels(myData)
```

5. Find the correlations of all of your data.

- Descriptively (just the values)

R code

```
lowerCor(myData)
```

- Graphically

R code

```
corPlot(myData) #show the numbers,
                #scales the character size by "significance"
corPlot(myData, scale=FALSE) #show the numbers,
                              # all characters the same size
corPlot(lowerCor(myData), numbers =TRUE) #print the correlations
                                          # and show them graphically
```

1.2 For the not impatient

The following pages are meant to lead you through the use of the `lmCor` and `mediate` functions. The assumption is that you have already made *psych* active and want some example code.

2 Multiple regression and mediation

Mediation and moderation are merely different uses of the linear model $\hat{Y} = \mu + \beta_{y,x}X + \varepsilon$ and are implemented in *psych* with two functions: `lmCor` and `mediate`.

Given a set of predictor variables, X and a set of criteria variables, Y , multiple regression solves the equation $\hat{Y} = \mu + \beta_{y,x}X$ by finding $\beta_{y,x} = C_{xx}^{-1}C_{yx}$ where C_{xx} is the covariances of the X variables and C_{yx} is the covariances of predictors and the criteria.

Although typically done using the raw data, clearly this can also be done by using the covariance or correlation matrices. `lmCor` was developed to handle the correlation matrix solution but has been generalized to the case of raw data. In the later case, it assumes a Missing Completely at Random (MCAR) structure, and thus uses all the data and finds pair.wise complete correlations. For complete data sets, the results are identical to using `lm`. By default, `lmCor` uses standardized variables, but to compare with `lm`, it can use unstandardized variables.

3 Regression using lmCor

Although typically done from a raw data matrix (using the `lm` function), it is sometimes useful to do the regression from a correlation or covariance matrix. `lmCor` was developed for this purpose. From a correlation/covariance matrix, it will do normal regression as well as regression on partialled correlation matrices. With the raw data, it will also do moderated regression (centered or non-centered). In particular, for the raw data, it will work with missing data.

An interesting option, if using categorical or dichotomous data is first find the appropriate polychoric, tetrachoric, or poly-serial correlations using `mixedCor` and then use the resulting correlation matrix for analysis. The resulting correlations and multiple correlations will not match those of the `lm` analysis.

3.1 Comparison with lm on complete data

We use the `attitude` data set for our first example.

3.1.1 It is important to know your data by describing it first

```
> psych::describe(attitude)
```

	vars	n	mean	sd	median	trimmed	mad	min	max	range	skew	kurtosis	se
rating	1	30	64.63	12.17	65.5	65.21	10.38	40	85	45	-0.36	-0.77	2.22
complaints	2	30	66.60	13.31	65.0	67.08	14.83	37	90	53	-0.22	-0.68	2.43
privileges	3	30	53.13	12.24	51.5	52.75	10.38	30	83	53	0.38	-0.41	2.23
learning	4	30	56.37	11.74	56.5	56.58	14.83	34	75	41	-0.05	-1.22	2.14
raises	5	30	64.63	10.40	63.5	64.50	11.12	43	88	45	0.20	-0.60	1.90
critical	6	30	74.77	9.89	77.5	75.83	7.41	49	92	43	-0.87	0.17	1.81
advance	7	30	42.93	10.29	41.0	41.83	8.90	25	72	47	0.85	0.47	1.88

3.1.2 Now do the regressions

```
> #do not standardize
> mod1 <- lmCor(rating ~ complaints + privileges, data=attitude, std=FALSE)
> mod1
```

Call: `lmCor(y = rating ~ complaints + privileges, data = attitude, std = FALSE)`

Multiple Regression from raw data

DV = rating	slope	se	t	p	lower.ci	upper.ci	VIF	Vy.x
(Intercept)	15.33	7.16	2.14	4.1e-02	0.64	30.02	1.00	0.00
complaints	0.78	0.12	6.54	5.2e-07	0.54	1.03	1.45	0.70
privileges	-0.05	0.13	-0.39	7.0e-01	-0.32	0.22	1.45	-0.02

Residual Standard Error = 7.1 with 27 degrees of freedom

Multiple Regression

	R	R2	Ruw	R2uw	Shrunken R2	SE of R2	overall F	df1	df2	p
rating	0.83	0.68	0.62	0.38	0.66	0.08	29.1	2	27	1.83e-07

Compare this solution with the results of the `lm` function.

```
> summary(lm(rating ~ complaints + privileges, data=attitude))
```

```
Call:
lm(formula = rating ~ complaints + privileges, data = attitude)

Residuals:
    Min       1Q   Median       3Q      Max

```

3.2 From a correlation matrix

Perhaps most usefully, `lmCor` will find the beta weights between a set of X variables, and a set of Y variables. Consider seven variables in the `attitude` data set. We first find the correlation matrix (normally, this could just be supplied by the user). Then we find the regressions from the correlation matrix. Compare this regression to the (standardized) solution shown above. By specifying the number of observations (`n.obs`), we are able to apply various inferential tests.

A simple regression model

Figure 1: A simple multiple regression using the attitude data set (standardized solution is shown).

R code

```
> R <- lowerCor(attitude)
```

```
          ratng cmpln prvlg lrnng raiss crtcl advnc
rating      1.00
complaints  0.83  1.00
privileges  0.43  0.56  1.00
learning    0.62  0.60  0.49  1.00
raises      0.59  0.67  0.45  0.64  1.00
critical    0.16  0.19  0.15  0.12  0.38  1.00
advance     0.16  0.22  0.34  0.53  0.57  0.28  1.00
```

R code

```
> lmCor(rating ~ complaints + privileges, data=R, n.obs =30)
```

Call: `lmCor(y = rating ~ complaints + privileges, data = R, n.obs = 30)`

Multiple Regression from matrix input

```
DV = rating
      slope  se      t      p lower.ci upper.ci VIF  Vy.x
complaints  0.85 0.13  6.54 5.2e-07  0.59  1.12 1.45  0.70
privileges -0.05 0.13 -0.39 7.0e-01 -0.32  0.22 1.45 -0.02
```

Residual Standard Error = 0.58 with 27 degrees of freedom

```
Multiple Regression
      R  R2  Row R2uw Shrunken R2 SE of R2 overall F df1 df2      p
rating 0.83 0.68 0.71 0.5 0.66 0.08 29.1 2 27 1.83e-07
```

Compare this solution (from the correlation matrix) with the *standardized* solution for the raw data. `lmCor` does several things:

- Finds the regression weights (betas) between the predictor variables and each of the criterion variables.
- If the number of subjects is specified, or if the raw data are used, it also compares each of these betas to its standard error, finds a t statistic, and reports the probability of the $t > 0$.
- It reports the Multiple R and R^2 based upon these beta weights. In addition, following the tradition of the robust beauty of the improper linear models (Dawes, 1979) it also reports the unit weighted multiple correlations.
- The canonical correlations between the two sets (Hotelling, 1936) is reported.
- Cohen's set correlation (Cohen, 1982) as well as the unweighted correlation between the two sets of variables are reported.

3.3 The Hotelling example

R code

```
> #the second Kelley data from Hotelling
> kelley <- structure(list(speed = c(1, 0.4248, 0.042, 0.0215, 0.0573), power = c(0.4248,
+ 1, 0.1487, 0.2489, 0.2843), words = c(0.042, 0.1487, 1, 0.6693,
+ 0.4662), symbols = c(0.0215, 0.2489, 0.6693, 1, 0.6915), meaningless = c(0.0573,
```

```
+ 0.2843, 0.4662, 0.6915, 1)), .Names = c("speed", "power", "words",
+ "symbols", "meaningless"), class = "data.frame", row.names = c("speed",
+ "power", "words", "symbols", "meaningless"))
> #first show the correlations
> lowerMat(kelley)
```

```
      speed power words symbol mnnngl
speed      1.00
power      0.42  1.00
words      0.04  0.15  1.00
symbols    0.02  0.25  0.67  1.00
meaningless 0.06  0.28  0.47  0.69  1.00
```

R code

```
> #now find and draw the regression
> sc <- lmCor(power + speed ~ words + symbols + meaningless,data=kelley) #formula mode
> sc #show it
```

Call: `lmCor(y = power + speed ~ words + symbols + meaningless, data = kelley)`

Multiple Regression from matrix input

```
DV = power
      slope VIF Vy.x
words   -0.03 1.81 -0.01
symbols  0.12 2.72  0.03
meaningless 0.22 1.92  0.06
```

```
Multiple Regression
      R  R2  Ruw R2uw
power 0.29 0.09 0.26 0.07
```

```
DV = speed
      slope VIF Vy.x
words    0.05 1.81  0
symbols  -0.07 2.72  0
meaningless 0.08 1.92  0
```

```
Multiple Regression
      R  R2  Ruw R2uw
speed 0.07 0.01 0.05  0
```

Various estimates of between set correlations

```
Squared Canonical Correlations
[1] 0.0946 0.0035
```

```
Average squared canonical correlation = 0.05
Cohen's Set Correlation R2 = 0.1
Unweighted correlation between the two sets = 0.18
```

A plot of the regression model is shown as well (Figure 2).

pdf
2

But, we can also do multiple predictors *and* multiple criteria in the same call:

pdf
2

The Kelley data set

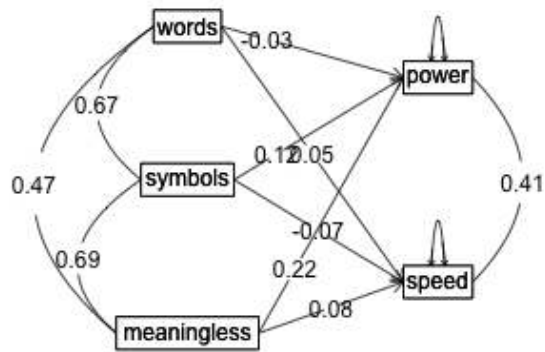

Figure 2: The relationship between three predictors and two criteria from `lmCor`. The data are from the Kelley data set reported by [Hotelling \(1936\)](#).

Regression Models

Figure 3: The relationship between three predictors and three criteria from `lmCor`. The data are from the `sat.act` data set.

3.4 Graphic displays

When considering the within group relationships for multiple groups, (e.g., gender or grade level) it is useful to draw separate regression lines for each group. Consider the case of the regression of age on paragraph comprehension as a function of class grade (6 or 7) in the `holzinger.swineford` data set in *psychTools*.

```
> lowerCor(holzinger.swineford[c(3,7,12:14)])
```

```

      grade agemo t05_g t06_p t07_s
grade      1.00
agemo      0.53  1.00
t05_geninfo 0.21 -0.15  1.00
t06_paracomp 0.21 -0.20  0.66  1.00
t07_sentcomp 0.18 -0.23  0.72  0.73  1.00

```

It would seem as if both age and grade account for 4% of the variance in paragraph comprehension. But combining these two in a multiple regression increases the variance explained from 8% (the sum of the two) to 18%, because age and grade suppress variance unrelated to cognitive performance.

We can show this finding in two different ways: as a plot of the separate regression lines Figure 5 or as a simple path model Figure ?? . Note that because grade goes from 7 to 8, to index the colors in the plot we subtract 6 from both grades to get a 1, 2 variable.

```
> png('hsp.png')
> lmCor(t07_sentcomp ~ agemo + grade, data=holzinger.swineford)
```

Call: `lmCor(y = t07_sentcomp ~ agemo + grade, data = holzinger.swineford)`

Multiple Regression from raw data

```

DV = t07_sentcomp
      slope se      t      p lower.ci upper.ci VIF Vy.x
(Intercept) 0.00 0.05  0.00 1.0e+00   -0.10    0.10 1.00 0.00
agemo      -0.46 0.06 -7.39 1.5e-12   -0.58   -0.34 1.39 0.11
grade       0.42 0.06  6.78 6.4e-11    0.30    0.54 1.39 0.07

```

Residual Standard Error = 0.91 with 298 degrees of freedom

Multiple Regression

```

      R  R2  Ruw R2uw Shrunken R2 SE of R2 overall F df1 df2      p
t07_sentcomp 0.43 0.18 0.42 0.18      0.18  0.04    32.97  2 298 1.16e-13

```

```
> dev.off()
```

pdf
2

```
> png('hs.png')
> plot(t07_sentcomp ~ agemo, col=c("red", "blue")[holzinger.swineford$grade -6],
+      pch=26-holzinger.swineford$grade, data=holzinger.swineford,
+      ylab="Sentence Comprehension", xlab="Age in Months",
```

Regression Models

Figure 4: The regression of age and grade on paragraph comprehension. The data are from the `holzinger:swineford` data set. Although age and grade are highly correlated ($.53$) grade has a positive effect age a negative effect. Here we show the standardized regressions. In the subsequent figure we show the raw (understanderized) slopes.

```
+ main="Sentence Comprehension varies by age and grade")
> by(holzinger.swineford, holzinger.swineford$grade -6,function(x) abline(
+ lmCor(t07_sentcomp ~ agemo,data=x, std=FALSE, plot=FALSE) ,lty=c("dashed","solid")[x$grade-6]))
```

```
holzinger.swineford$grade - 6: 1
NULL
```

```
holzinger.swineford$grade - 6: 2
NULL
```

R code

```
> text(190,3.3,"grade = 8")
> text(190,2,"grade = 7")
> dev.off()
```

pdf
2

To show the coefficients of this model, we do the regressions without the plot.

R code

```
> by(holzinger.swineford,holzinger.swineford$grade,function(x)
+ lmCor(t07_sentcomp ~ agemo,data=x, std=FALSE, plot=FALSE) )
```

```
holzinger.swineford$grade: 7
Call: lmCor(y = t07_sentcomp ~ agemo, data = x, std = FALSE, plot = FALSE)
```

Multiple Regression from raw data

```
DV = t07_sentcomp
      slope  se    t      p lower.ci upper.ci VIF Vy.x
(Intercept) 12.10 1.37  8.83 2.1e-15    9.39    14.81   1 0.00
agemo       -0.05 0.01 -5.83 3.0e-08   -0.07    -0.03   1 0.18
```

Residual Standard Error = 1.15 with 155 degrees of freedom

Multiple Regression

```
      R  R2  Ruw R2uw Shrunken R2 SE of R2 overall F df1 df2      p
t07_sentcomp 0.42 0.18 -0.3 0.09    0.17    0.05    34.04   1 155 3.05e-08
```

```
holzinger.swineford$grade: 8
Call: lmCor(y = t07_sentcomp ~ agemo, data = x, std = FALSE, plot = FALSE)
```

Multiple Regression from raw data

```
DV = t07_sentcomp
      slope  se    t      p lower.ci upper.ci VIF Vy.x
(Intercept) 12.09 1.64  7.38 1.2e-11    8.85    15.33   1 0.00
agemo       -0.04 0.01 -4.59 9.5e-06   -0.06    -0.03   1 0.13
```

Residual Standard Error = 1.2 with 142 degrees of freedom

Multiple Regression

```
      R  R2  Ruw R2uw Shrunken R2 SE of R2 overall F df1 df2      p
t07_sentcomp 0.36 0.13 -0.25 0.06    0.12    0.05    21.11   1 142 9.5e-06
```

Figure 5: Showing a multiple regression using `lmCor` with lines for each group. The data are from the `holzinger:swineford` data set. Although age and grade are highly correlated (.53) grade has a positive effect age a negative effect.

3.5 Moderated multiple regression

If we have the raw data, we can also find interactions (known as moderated multiple regression). This is done by zero centering the data (Cohen et al., 2003) and then multiplying the two terms of the interaction. As an option, we can not zero center the data (Hayes, 2013) which results in different “main effects” but the same interaction term. To show the equivalence of the interaction terms, we also must not standardize the results.

We use the `globalWarm` data set taken from (Hayes, 2013)

```

> mod <-lmCor(govact ~ negemot * age + posemot +ideology+sex,data=globalWarm,
+             std=FALSE, zero=FALSE, plot=FALSE)
> mod

```

Call: `lmCor(y = govact ~ negemot * age + posemot + ideology + sex, data = globalWarm, std = FALSE, plot = FALSE, zero = FALSE)`

Multiple Regression from raw data

```
DV = govact
```

	slope	se	t	p	lower.ci	upper.ci	VIF	Vy.x
(Intercept)	5.17	0.34	15.29	1.6e-46	4.51	5.84	1.00	0.00

not zero centered

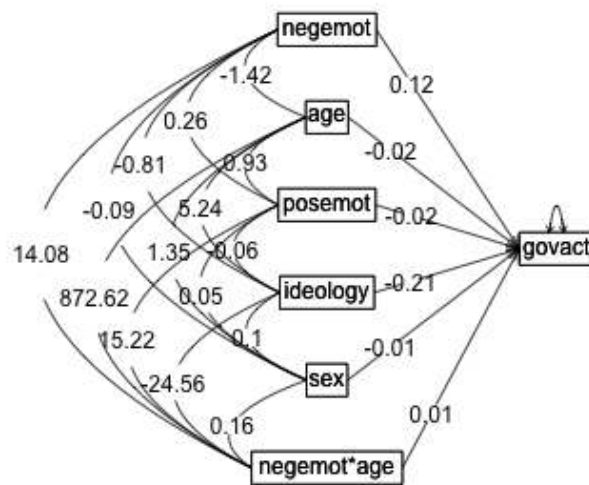

Figure 6: Showing a moderated multiple regression using `lmCor`. The data are from the `globalWarm` data set.

3.6 Plotting the interactions

To visualize the effect of zero (mean) centering, it is useful to plot the various elements that go into the linear model. `lmCor` returns the product terms as well as the original data. I combine the two datasets to make it clearer. Note that the correlations of the centered age, negemot with the

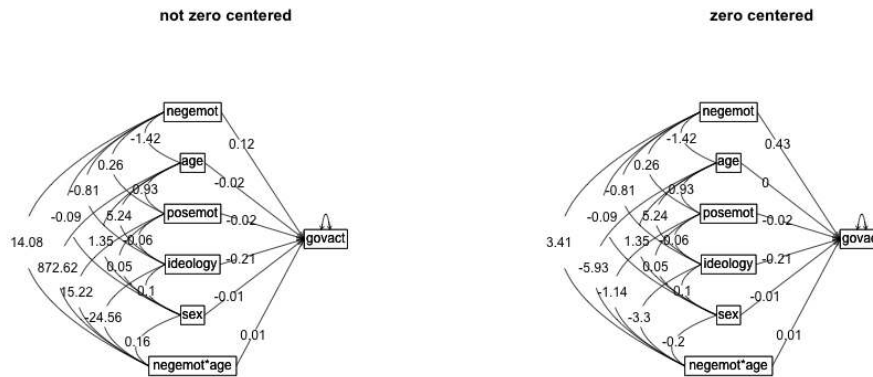

Figure 7: The difference between 0 and not 0 centering `lmCor`. The data are from the `globalWarm` data set. In both cases, the data are not standardized.

uncentered are 1.0, but that the correlations with the product terms depend upon centering versus not. I drop the some of the other variables from the figure for clarity (Figure 8).

pdf
2

3.7 Comparisons to `lm`

The `lmCor` function duplicates the functionality of the `lm` function for complete data, although `lm` does not zero center and `lmCor` will (by default). In addition, `lmCor` finds correlations based upon pair.wise deletion of missing data, while `lm` does case.wise deletion. We compare the `lm` and `lmCor` results for complete data by setting the `use = "complete"` option. We use the `sat.act` data set which has some missing values.

4 Mediation using the mediate function

Mediation analysis is just linear regression reorganized slightly to show the direct effects of an X variable upon Y, partialling out the effect of a “mediator” (Figure 9). Although the statistical “significance” of the (c) path and the (c’) path are both available from standard regression, the mediation effect (ab) is best found by bootstrapping the regression model and displaying the empirical confidence intervals.

A number of papers discuss how to test for the effect of mediation and there are some very popular ‘macros’ for SPSS and SAS to do so (Hayes, 2013; Preacher and Hayes, 2004; Preacher et al., 2007; Preacher, 2015). A useful discussion of mediation and moderation with sample data sets is found in Hayes (2013). More recently, the *processR* package (Moon, 2020) has been released with these data sets. Although these data used to be available from <http://www.afhayes.com/public/hayes2018data.zip> this now longer seems to be case.¹ I use these for comparisons with the results in Hayes (2013). Four of these data sets are now included in the *psych* package with the kind permission of their

¹The Hayes data sets (2018) do not correspond exactly with those from the 2013 book. Those data files were at <http://www.afhayes.com/public/hayes2013data.zip>.

Figure 9: The classic mediation model. The Direct Path from $X \rightarrow Y$ (c) is said to be mediated by the indirect path (a) to the mediator ($X \rightarrow M$) and (b) from the mediator to Y ($M \rightarrow Y$). The mediation effect is (ab).

authors: `Garcia` is from [Garcia et al. \(2010\)](#), and `Tal_Or` is from [Tal-Or et al. \(2010\)](#), The `Pollack` correlation matrix is taken from an article by [Pollack et al. \(2012\)](#). The `globalWarm` data set is the `glbwarm` data set in the `processR` package and added to `psychTools` with the kind permission of the original author, Erik Nisbet.

To find the confidence intervals of the effect of mediation (the reduction between the c and c' paths, where $c' = c - ab$), I bootstrap the results by randomly sampling from the data with replacement (`n.iter = 5000`) times.

For these examples, the data files `Garcia` ([Garcia et al., 2010](#)) and `Tal_Or` ([Tal-Or et al., 2010](#)) are included in the `psych` package. The `estrss` data set and `globalWarm` were originally downloaded from the [Hayes \(2013\)](#) data set and stored in a local directory on my computer. They are now available from the `processR` package [Moon \(2020\)](#).

The syntax is that $y \sim x + (m)$ where m is the mediating variable. By default the output is to two decimals, as is the graphic output. This can be increased by returning the output to an object and then printing that object with the desired number of decimals.

4.1 Simple mediation

The first example ([Hayes, 2013](#), mod.4.5) is taken from ([Tal-Or et al., 2010](#)) and examines the mediating effect of “Presumed Media Influence” (`pmi`) on the intention to act (`reaction`) based

upon the importance of a message (import). The data are in the `Tal_Or` data set in *psych* (with the kind permission of Nurit Tal-Or, Jonanathan Cohen, Yariv Tasfati, and Albert Gunther). In the [Hayes \(2013\)](#) book, this is the `pmi` data set.

```
R code
> data(Tal.Or)
> psych::describe(Tal_Or) #descriptive statistics
```

	vars	n	mean	sd	median	trimmed	mad	min	max	range	skew	kurtosis	se
cond	1	123	0.47	0.50	0.00	0.46	0.00	0	1	1	0.11	-2.00	0.05

4.2 Multiple mediators

It is trivial to show the effect of multiple mediators. I do this by adding the second (or third) mediator into our equation. I use the `Tal_Or` data set (Tal-Or et al., 2010) again. I show the graphical representation in Figure 11.

```

R code
> mod5.4 <- mediate(reaction ~ cond + (import) + (pmi), data = Tal_Or)
> print(mod5.4, digits=4) #to compare with Hayes

```

Mediation/Moderation Analysis

```
Call: mediate(y = reaction ~ cond + (import) + (pmi), data = Tal_Or)
```

```
The DV (Y) was reaction . The IV (X) was cond . The mediating variable(s) = import pmi .
```

```

Direct effect (c') of cond on reaction removing import pmi = 0.1034 S.E. = 0.2391 t = 0.4324 d
Indirect effect (ab) of cond on reaction through import pmi = 0.3923
Mean bootstrapped indirect effect = 0.3941 with standard error = 0.1634 Lower CI = 0.0873 Upper CI =
R = 0.5702 R2 = 0.3251 F = 19.1118 on 3 and 119 DF p-value: 3.6636e-12
```

To see the longer output, specify `short = FALSE` in the print statement or ask for the summary

```

R code
>

```

pdf
2

4.3 Serial mediators

The example from Hayes (2013) for two mediators, where one effects the second, is a bit more complicated and currently can be done by combining two separate analyses. The first is just model 5.4, the second is the effect of `cond` on `pmi` mediated by `import`.

Combining the two results leads to the output found on (Hayes, 2013, page 153).

pdf
2

```

R code

4.4 Single mediators, multiple covariates

The Pollack data set (Pollack et al., 2012) is used as an example of multiple covariates (included in *psychTools* as a correlation matrix). The raw data are available from the *processR* package as *estress*. Confidence in executive decision making (“Entrepreneurial self-efficacy), gender (sex), and length of time in business (tenure) are used as covariates. There are two ways of doing this: enter them as predictors of the criterion or to partial them out. The first approach estimates their effects, the second just removes them.

R code

```

> lowerMat(Pollack)

sex      sex  age  tenur slf.f cmptn scl.t ecnm. dprss withdr

The graphical output (Figure 12) looks a bit more complicated than the figure in (Hayes, 2013, p 177) because I am showing the covariates as causal paths.

4.5 Single predictor, single criterion, multiple covariates

An alternative way to display the previous results is to remove the three covariates from the mediation model. I do this by partialling out the covariates. This is represented in the `mediate` code by a negative sign. (Figure 13)

```

R code
> mod6.2a <- mediate(withdrawal ~ economic.stress -self.efficacy - sex - tenure + (depression),
+ data=Pollack, n.obs=262)
> summary(mod6.2a)

```

```

Call: mediate(y = withdrawal ~ economic.stress - self.efficacy - sex -
tenure + (depression), data = Pollack, n.obs = 262)

```

```

Direct effect estimates (traditional regression) (c') X + M on Y

```

Simple mediation, 3 covariates

Figure 12: A mediation model with three covariates (Hayes, 2013, p 177). Compare this to the solution in which they are partialled out. (Figure 13).

4.6 Multiple predictors, single criterion

It is straightforward to use multiple predictors see (Hayes, 2013, p196) and in fact I did so in the previous example where the predictors were treated as *covariates*. `mediate` also allows for multiple criteria.

5 Mediation and moderation

We already saw how to do moderation in the discussion of `setCor`. Combining the concepts of mediation with moderation is done in `mediate`. That is, I can find the linear model of product terms as they are associated with dependent variables and regressed on the mediating variables.

The Garcia data set (Garcia et al., 2010) can be used for an example of moderation. (This was taken from (Hayes, 2013) but is used with kind permission of Donna M. Garcia, Michael T. Schmitt, Nyla R. Branscombe, and Naomi Ellemers.) Just as `setCor` and `lm` will find the interaction term by forming a product, so will `mediate`. Notice that by default, `setCor` reports zero centered and standardized regressions, `mediate` reports zero centered but not standardized regressions, and some of the examples from Hayes (2013) do not zero center the data. Thus, I specify `zero=FALSE` to get the Hayes (2013) results.

It is important to note that the `protest` data set discussed here is from the 2013 examples and not

Simple mediation, 3 covariates (partialled out)

Figure 13: Show the mediation model from Figure 12 with the covariates (ese, sex, tenure) removed.

the more recent 2018 examples available from afhayes.com. The 2013 data have a dichotomous protest variable, while the 2018 data set has three levels for the protest variable. The Garcia data set is composed of the 2018 data set with the addition of a dichotomous variable (prot2) to match the 2013 examples.

We consider how the interaction of sexism with protest affects the mediation effect of sexism (Hayes, 2013, p 362), I contrast the `lm`, `setCor` and `mediate` approaches. For reasons to be discussed in the next section, I do not zero center the variables. The graphic output is in Figure 14 and the output is below. For comparison purposes, I show the results from the `lm` as well as `setCor` and `mediate`.

```

5.1 To center or not to center, that is the question

We have discussed the difference between zero centering and not zero centering. Although [Hayes \(2013\)](#) seems to prefer not centering, some of his examples are in fact centered. So, when we examine Table 8.2 and try to replicate the regression, we need to zero center the data.

With the global warming data from [Hayes \(2013\)](#), the default (uncentered) regression does not reproduce his Table, but zero centering does. To this in `lm` requires two steps, but we can do this in `setCor` with the `zero=TRUE` or `zero=FALSE` option.

R code

```
> lm(govact ~ age * negemot + posemot + ideology + sex, data=globalWarm)
```

An example of moderated mediation

Figure 14: Moderated mediation from (Hayes, 2013, p 362). The data are from Garcia et al. (2010).

```
Call:
lm(formula = govact ~ age * negemot + posemot + ideology + sex,
    data = globalWarm)
```

```
Coefficients:
(Intercept)      age      negemot      posemot      ideology      sex  age:negemot
  5.173849   -0.023879   0.119583   -0.021419   -0.211515   -0.011191   0.006331
```

```
> # but zero center and try again
> glbwarmc <- data.frame(scale(globalWarm, scale=FALSE))
> lm(govact ~ age * negemot + posemot + ideology + sex, data=globalWarm)
```

```
Call:
lm(formula = govact ~ age * negemot + posemot + ideology + sex,
    data = globalWarm)
```

```
Coefficients:
(Intercept)      age      negemot      posemot      ideology      sex  age:negemot
  5.173849   -0.023879   0.119583   -0.021419   -0.211515   -0.011191   0.006331
```

```
> mod.glb <- setCor(govact ~ age * negemot + posemot + ideology + sex, data=globalWarm, zero=FALSE, std=FALSE)
> print(mod.glb, digits=6)
```

```
Call: setCor(y = govact ~ age * negemot + posemot + ideology + sex,
             data = globalWarm, std = FALSE, zero = FALSE)
```

```

Compare this output to that of Table 8.2 and Figure 8.5 (p 258 - 259).

5.2 Another example of moderated mediation

The Garcia data set (protest in Hayes (2013)) is another example of a moderated analysis. We can use either `setCor` or `mediate` to examine this data set. The defaults for these two differ, in that `setCor` assumes we want to zero center *and* standardize, while `mediate` defaults to not standardizing but also defaults to zero (mean) centering. Note that in the next examples we specify we do not want to standardize nor to mean center.

```
> psych::describe(Garcia)
```

	vars	n	mean	sd	median	trimmed	mad	min	max	range	skew	kurtosis	se
protest	1	129	1.03	0.82	1.00	1.04	1.48	0.00	2	2.00	-0.06	-1.52	0.07

5.3 Graphic Displays of Interactions

In order to graphically display interactions, particularly if one of the variable is categorical, we can plot separate regression lines for each value of the categorical variable. We do this for the *Garcia* data set to show the interaction of protest with sexism. (see Figure 16). This is just an example of how to use Core-R to do graphics and is not a feature of *psych*.

R code

```

> png('garciainteraction.png')
> plot(respappr ~ sexism, pch = 23- protest, bg = c("black","red", "blue")[protest],
+ data=Garcia, main = "Response to sexism varies as type of protest")
> by(Garcia,Garcia$protest, function(x) abline(lm(respappr ~ sexism,
+ data =x), lty=c("solid", "dashed", "dotted")[x$protest+1]))

```

```

Garcia$protest: 0
NULL

```

```

-----
Garcia$protest: 1
NULL

```

```

-----
Garcia$protest: 2
NULL

```

R code

```

> text(6.5,3.5,"No protest")
> text(3,3.9,"Individual")
> text(3,5.2,"Collective")
> dev.off()

```

pdf
2

R code

```

>

```

Another example of moderated mediation

Figure 15: A simple moderated regression analysis of the `protest` data set. The data were not zero centered. This shows the strength of the three regressions. Figure 16 shows the actual data and the three regression lines.

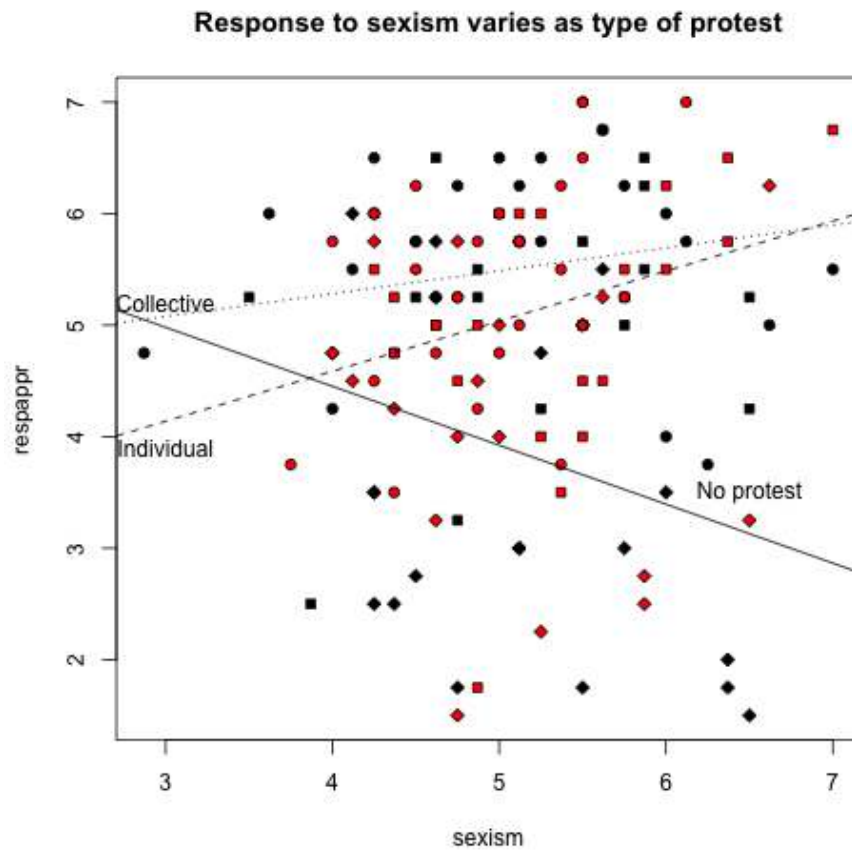

Figure 16: Showing the interaction between type of protest and sexism from the Garcia data set. The strength of the regression effects is shown in Fig 15.

6 Partial Correlations

Although not strictly speaking part of mediation or moderation, the use of *partial correlations* can be addressed here. s

6.1 Partial some variables from the rest of the variables

Given a set of X variables and a set of Y variables, we can control for an additional set of Z variables when we find the correlations between X and Y. This is effectively what happens when we want to add covariates into a model. We see this when we compare the regression model for government action as a function of the interaction of ideology and age with some covariates, or when we partial them out first.

```
R code
> #first, the more complicated model
> mod.glb <- setCor(govact ~ age * negemot + posemot + ideology + sex,
+                 data=globalWarm, std=FALSE)
> print(mod.glb, digits=3)
```

```
Call: setCor(y = govact ~ age * negemot + posemot + ideology + sex,
            data = globalWarm, std = FALSE)
```

Multiple Regression from raw data

```
DV = govact
      slope   se      t      p lower.ci upper.ci  VIF  Vy.x
(Intercept) 4.596 0.037 123.917 0.00e+00  4.523  4.669 1.000 0.000
age         -0.001 0.002  -0.577 5.64e-01 -0.006  0.003 1.071 0.002
negemot      0.433 0.026  16.507 5.76e-53  0.382  0.485 1.172 0.281
posemot     -0.021 0.028  -0.768 4.43e-01 -0.076  0.033 1.029 -0.001
ideology    -0.212 0.027  -7.883 1.04e-14 -0.264 -0.159 1.199 0.098
sex         -0.011 0.076  -0.147 8.83e-01 -0.160  0.138 1.053 0.000
age*negemot 0.006 0.002  4.104 4.48e-05  0.003  0.009 1.015 0.020
```

Residual Standard Error = 1.057 with 808 degrees of freedom

```
Multiple Regression
      R    R2  Ruw R2uw Shrunken R2 SE of R2 overall F df1 df2      p
govact 0.633 0.401 0.356 0.127      0.396 0.026  90.08  6 808 1.825e-86
```

```
R code
> # compare this to the partialled model
>
> mod.glb.partialled <- setCor(govact ~ age * negemot - posemot - ideology - sex, data = globalWarm)
>
```

Note how the beta weights for the age, negemot and interaction terms are identical.

6.2 Partial everything from everything

Sometimes we want to examine just the independent effects of all our variables. That is to say, we want to partial all the variables from all the other variables. I do this with the `partial.r` function. To show the results, I compare the partialled rs to the original rs. I show the lower off

diagonal matrix using `lowerMat`. Then to compare the partial matrix to the original matrix, I form the square matrix where the lower off diagonal is the original matrix and the upper off diagonal is the partial matrix.

R code

```
> upper <- partial.r(globalWarm)
> lowerMat(upper) #show it
```

```
      govct posmt negmt idlgy age  sex  prtyd
govact  1.00
posemot -0.03  1.00
negemot  0.50  0.13  1.00
ideology -0.19  0.00 -0.07  1.00
age     -0.02  0.04  0.03  0.14  1.00
sex      0.00  0.08 -0.07  0.04  0.14  1.00
partyid -0.08 -0.01 -0.09  0.53  0.03  0.02  1.00
```

R code

```
> lower <- lowerCor(globalWarm)
```

```
      govct posmt negmt idlgy age  sex  prtyd
govact  1.00
posemot  0.04  1.00
negemot  0.58  0.13  1.00
ideology -0.42 -0.03 -0.35  1.00
age     -0.10  0.04 -0.06  0.21  1.00
sex      -0.10  0.07 -0.12  0.13  0.17  1.00
partyid -0.36 -0.04 -0.32  0.62  0.15  0.11  1.00
```

R code

```
> lowup <- lowerUpper(lower, upper)
>
```

pdf

7 Related packages

`mediate` and `setCor` are just two functions in the *psych* package. There are several additional packages available in R to do mediation. The *mediation* package (Tingley et al., 2014) seems the most powerful, in that is tailor made for mediation. *MBESS* (Kelley, 2017) has a mediation function. Steven Short has a nice tutorial on mediation analysis available for download [that discusses how to use R for mediation](#). And, of course, the *lavaan* package (Rosseel, 2012) is the recommended package to do SEM and path models.

Figure 17: Correlations (below diagonal) and partial correlations (above the diagonal)

8 Development version and a users guide

The *psych* package is available from the CRAN repository. However, the most recent development version of the *psych* package is available as a source file at the repository maintained at <http://personality-project.org/r>. That version will have removed the most recently discovered bugs (but perhaps introduced other, yet to be discovered ones). To install this development version, either for PCs or Macs,

```
install.packages("psych", repos = "http://personality-project.org/r", type = "source")
```

After doing this, it is important to restart R to get the new package.

Although the individual help pages for the *psych* package are available as part of R and may be accessed directly (e.g. `?psych`), the full manual for the *psych* package is also available as a pdf at http://personality-project.org/r/psych_manual.pdf

News and a history of changes are available in the NEWS and CHANGES files in the source files. To view the most recent news,

```
> news (Version >= "2.0.12", package="psych")
```

9 Psychometric Theory

The *psych* package has been developed to help psychologists do basic research. Many of the functions were developed to supplement a book (<http://personality-project.org/r/book> An introduction to Psychometric Theory with Applications in R (Revelle, prep) More information about the use of some of the functions may be found in the book .

For more extensive discussion of the use of *psych* in particular and R in general, consult http://personality-project.org/r/r_guide.html A short guide to R.
